build a GUI

- Qt is a cross-platform application and UI framework in C++.
- Using Qt, one can write GUI applications once and deploy them across desktop, mobile and embedded operating systems without rewriting the source code.
- Qt is supported on a variety of 32-bit and 64-bit platforms (Desktop, embedded, mobile):
 - Windows (MinGW, MSVS)
 - Linux (gcc)
 - Apple Mac OS
 - Mobile / Embedded (Windows CE, Windows Mobile, Symbian, Embedded Linux)

- Language bindings are available in C#, Java, Python(PyQt), Ada, Pascal, Perl, PHP(PHP-Qt), Ruby(RubyQt).
- Qt is available under GPL v3, LGPL v2 and commercial license.
- Real applications developed using Qt: Google Earth, KDE (desktop environment for Unix-like OS), Adobe Photoshop Album.
- Qt documentation: <http://doc.qt.io/qt-5/>.

Please see the tutorial on how to install Qt Library at
www.cs.ubbcluj.ro/~iuliana/oop/Setting_up_Qt5_with_Visual_Studio_2015.pdf

- Qt can be used with Microsoft Visual Studio as well as with Eclipse (provided there is a C++ compiler installed).
- There is also an IDE which is part of the SDK for the Qt GUI Application development framework - **QtCreator**. This also needs a C++ compiler.

Common
pattern to
build a GUI

- Create a new Qt application, as described in the tutorial mentioned on the previous slide.
- Edit the file *main.cpp*: add a new **QLabel** and display it, as follows:

```
#include <QtWidgets/QApplication>
#include <QtWidgets/QLabel>

int main(int argc , char *argv [])
{
    QApplication a(argc , argv);
    QLabel label("Hello world!");
    label.show();
    return a.exec();
}
```

Qt Designer

Common
pattern to
build a GUI

- The **QApplication** class manages the GUI application's control flow and main settings.
- **QApplication** contains the main event loop, where all events from the window system and other sources are processed and dispatched.
- For any GUI application using Qt, there is exactly one **QApplication** object (no matter whether the application has 0, 1, 2 or more windows at any given time). This object is accessible using the function **instance()**.

- Responsibility:
 - initializes the application with the user's desktop settings;
 - takes care of the *event loop*: performs event handling, it receives events from the underlying window system and dispatches them to the relevant widgets;
 - knows about the application's windows;
 - defines the application's look and feel.

Qt Designer

Common
pattern to
build a GUI

- For non-GUI Qt applications, use `QCoreApplication` instead.
- The `exec()` method of the `QApplication` makes the application enter its *event loop*.
- When a Qt application is running, the event loop waits for user input, then events are generated and sent to the widgets of the application.
- The loop is terminated when any of the functions `exit()` or `quit()` is called.

Qt Designer

Common
pattern to
build a GUI

- Widgets are the basic building blocks for graphical user interface (GUI) applications built with Qt. E.g.: buttons, labels, textboxes, etc.
- A GUI component (widget) can be placed on the user interface window or can be displayed as independent window.
- A widget that is not embedded in a parent widget is called a window.
- Windows provide the screen space upon which the user interface is built.

Qt Designer

Common
pattern to
build a GUI

- Windows visually separate applications from each other and usually provide a window decoration (show a title bar, allows the user to resize, position, etc).
- The Widgets module in Qt uses inheritance.
- All widgets inherit from **QWidget**, which is derived from **QObject**.

Qt Designer

Common
pattern to
build a GUI

- Widgets use the *parenting system*:
 - Any object that inherits from **QObject** can have a parent and children.
 - When an object is destroyed, all of its children are destroyed as well.
 - All QObjects have methods that allow searching the object's children.
 - Child widgets in a QWidget automatically appear inside the parent widget.

QLabel

- **QLabel** is used for displaying text or an image.
- No user interaction functionality is provided.
- A **QLabel** is often used as a label for an interactive widget.
- For this use **QLabel** provides a useful mechanism for adding an mnemonic that will set the keyboard focus to the other widget (called the **QLabel**'s "buddy").
- Is defined in the header `<QLabel>`.

```
QLabel label("Hello :)");  
label.show();
```

QLineEdit

- **QLineEdit** widget is a one-line text editor.
- A line edit allows the user to enter and edit a single line of plain text with a useful collection of editing functions, including undo and redo, cut and paste, and drag and drop.
- A related class is **QTextEdit** which allows multi-line, rich text editing.
- Is defined in the header `<QLineEdit>`.

```
QLineEdit lineEdit;  
QLabel label("&Hello :)");  
label.setBuddy(&lineEdit);
```

QPushButton

- The `QPushButton` widget provides a command button.
- Push (click) a button to command the computer to perform some action.
- Push buttons display a textual label, and optionally a small icon. A shortcut key can be specified by preceding the preferred character with an ampersand.
- Is defined in the header `<QPushButton>`.

QListWidget

- The `QListWidget` widget provides an item-based list widget.
- The widget presents a list of items to the user.
- `QListWidget` uses an internal model to manage each item in the list (`QListWidgetItem`).
- Is defined in the header `<QListWidget>`.

Layout
management

Qt Designer

Common
pattern to
build a GUI

- The Qt layout system provides a way to automatically arrange child widgets within a widget to ensure that they make good use of the available space.
- Qt includes a set of layout management classes that are used to describe how widgets are laid out in an application's user interface.
- These layouts automatically position and resize widgets when the amount of space available for them changes, ensuring that they are consistently arranged and that the user interface as a whole remains usable.

- Widgets are layed out in a two column form.
- The left column contains labels and the right column contains widgets.

The screenshot shows a Qt window titled "Lecture9_demo...". Inside the window, there is a form layout with three rows. Each row consists of a label on the left and a text input field on the right. The labels are "Name:", "Age:", and "Email:", each with its first letter underlined. The input fields are empty.

Layout
management

Qt Designer

Common
pattern to
build a GUI

- Widgets are layed out in a grid.
- The space is divided into rows and columns and each widget is put in the specified cell.
- It is also possible for a widget to occupy multiple cells by spanning the row/column.

DEMO

QGridLayout (*Lecture9_demo_widgets* - function *gridLayout*).

Layout and widgets' combinations

- Multiple widgets can be nested and different layouts can be used to create a GUI.

Qt Designer

Common
pattern to

- They provide a consistent behavior across different screen sizes and styles.
- Layout managers handle resize operations.
- They automatically adapt to different fonts and platforms. If the user changes the systems font settings, the applications forms will respond immediately, resizing themselves if necessary.

Qt Designer

Common
pattern to

- They automatically adapt to different languages. If the applications user interface is translated to other languages, the layout classes take into consideration the widgets translated contents to avoid text truncation.
- If a widget is added to or removed from a layout, the layout will automatically adapt to the new situation (the same thing happens when applying the *show()* or *hide()* functions for a widget).

Absolute positioning I

Object-

Programming

Iuliana
Bocicor

Qt toolkit

QApplication

Qt GUI
Components
(widgets)

Layout
management

Qt Designer

Common
pattern to
build a GUI

- An absolute position can be specified for a widget using the function `setGeometry()`, which builds a rectangle using the given parameters (x and y positions, width and height).

Absolute positioning disadvantages

- If the window is resized, the widgets with absolute positions remain unchanged.
- Some text may be truncated (large font or change in the labels).
- The positions and sizes must be calculated manually (error-prone, hard to maintain).

Qt Designer

Common
pattern to
build a GUI

- Qt Designer is the Qt tool for designing and building GUIs.
- Windows and dialogs can be designed in a what-you-see-is-what-you-get manner.
- Objects can be dragged from the widget box and dropped on the form.
- Object properties can be modified interactively.

Qt Designer

Common
pattern to
build a GUI

- Using the Qt Designer can be faster than hand-coding the interface.
- One can experiment with different designs quickly.
- A **.ui** file is created, representing the widget tree of the form in XML format. This file can be used at compile time to generate C++ code that can be compiled.

- When the elements in the dialog must change dynamically.
- When we want to use custom widgets.

How?

- 1 Create a new class, by inheriting from **QWidget**.
- 2 Implement the GUI.
- 3 Show the newly created widget.

Common
pattern to
build a GUI

- ❶ Instantiate the required Qt widgets.
- ❷ Set properties for these, if necessary.
- ❸ Add the widgets to a layout (the layout manager will take care of the position and size).
- ❹ Connect the widgets using the signal and slot mechanism (will be presented next week).
